1 PROBLEM

Modify the following code given in problem 2.3 with different input parameters to get the best possible output.

import soundfile as sf from scipy import signal

#read .wav file
input_signal,fs = sf.read('Sound_Noise.wav')

#sampling frequency of Input signal sampl freq=fs

#order of the filter order = 3

#cutoff frequency 4kHz cutoff freq=4000.0

#digital frequency
Wn=2*cutoff_freq/sampl_freq

b and a are numerator and denominator polynomials respectivelyb, a = signal.butter(order, Wn, 'low')

#filter the input signal with butterworth filter
output_signal = signal.filtfilt(b, a, input_signal)
#output_signal = signal.lfilter(b, a, input_signal)

#write the output signal into .wav file
sf.write('Sound_With_ReducedNoise.wav',
 output_signal, fs)

2 Solution

The main parameters for a standard Butterworth filter are

- Cutoff frequency
- Order

2.1 Cutoff Frequency

Cutoff frequency for a Butterworth filter is the -3dB point after which all the frequency components roll off down to zero.

To select a good cutoff frequency, we observe the spectogram from Problem 2.2 and conclude that most of the frequencies corresponding to piano notes are around mid point of 440Hz and 4700Hz, so let the cutoff frequency be (440 + 4700)/2 = 2570Hz.

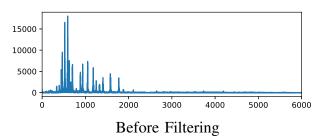

2.2 Order

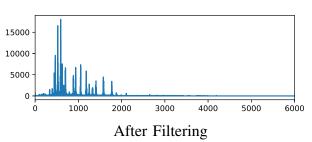

The main disadvantage of the Butterworth filter is that it achieves the pass band flatness at the expense of a wide transition band as the filter changes from the pass band to the stop band.

We can fix this by increasing the order, but having a very high order would create numerical instabilities while simulating. So we will stick to the general order 4.

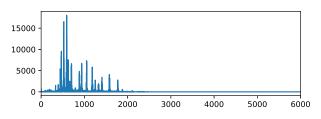

3 RESULTS

After applying the filter with above parameters we observe that we still have noise. The frequency response of signal before and after applying the filter shows that the transition region is too wide, there are too many non zero frequency components after the cutoff frequency.

To overcome this we would need a steeper transition. Since we cant increase the order, one solution is to cascade multiple butterworth filters. The transfer function rolls off to zero from pass band to stop band, as we cascade more and more filters the gain values< 1 would get multiplied and reach closer to zero.

After Cascaded Filtering

Parameter	Original	Filtered	Cascaded
Cutoff Frequency	2570Hz	2570Hz	2570 <i>Hz</i>
Order	-	4	4
No. of Cascades	-	0	19
Fraction of signal	82.35%	97.38%	99.51%
before cutoff			
Fraction of signal	17.64%	2.61%	0.485%
after cutoff			

To get a better understanding of the noise present in the signal we sum up all the non zero frequency components before and after the cutoff frequency to define the metric fraction which tells us how much non zero frequency component is present before and after the cutoff Code used to generate the plots can be found at -
